Three-screw low-pressure pumps EAB EAD

Application

Three-screw pumps EAB and EAD are intended for clean oils forced pumping in various lubricating, cooling and low-pressure oil hydraulic systems of machinery and further equipments. They may also deliver further self-lubricating non-corrosive liquids without mechanical impurities. Those pumps are available for gearboxes, diesel engines, gas turbines, compressors, machine tools, and so on.

Max. delivery pressure 10 bar

Max. temperature of a pumped liquid 80 °C

Kinematic viscosity

of a pumped liquid ranging from 21,5 to 385 mm².s⁻¹

Workmanships

According to a drive version and their application those low-pressure three-screw pumps are available in following workmanships:

Workmanship EAB is intended for so-called „derived“ drive, direct from the respective machine or equipment with the aid of a gear drive. That pump is of glandless type, so that penetrated oil may flow back to the machine on which that pump has been fitted. The pump shaft drive end is of a tapered type.

Workmanship EAD - it is direct driven by its own electric motor, with transmission of a torque onto the pump shaft through a flexible coupling. Pump seal is formed by a radial lip seal. On a special request there a mechanical seal may be used. Oil from the seal space may be removed through a relief valve back to the suction side. The whole pump-set shall be seated on a foundation with its feet on the foot mounted lantern bracket placed between the pump and an electric motor.

Construction

Pumps EAB and EAD are of positive-displacement rotary three-screw type, with circular fixing flange. As the pump basic functional part there are three screws, the middle of which is the driving one, two lateral screws are driven by mutual engagements. Axial force of driven screws is taken up by rolling-contact bearings. Lubrication of all friction areas is with a pumped liquid.

Pump model key

65 - EAD - 52 N - 10 - LO - 020

65 Discharge branch I.D.

EAD Series designation

52 Driving screw adendum circle dia. in mm

N Screw lead designation

10 Tenfold of max. manometric pressure on the pump discharge side in bar

LO Material option number

020 Number of alteration, pump clockwise version, seal - radial lip seal ring „gufero“

Number of alteration 080 - counterclockwise pump version, sealing - radial lip seal ring „gufero“

Number of alteration 010 - clockwise pump version, sealing - soft gland packing

Number of alteration 030 - clockwise pump version, mechanical seal

Working positions

Pumps may work reliably in both vertical and horizontal positions. With the EAD workmanship with an electric motor, that is, as an pump-set, there horizontal working position may be considered to be the standard one. Provided, that pump-set is supplied in its vertical arrangement, it is intended for attachment to a foundation or mounting on a tank with the lower flange of the lantern bracket.

To make arrangement of pump branches in various positions possible, it is recommended to turn the pump to the left and/or to the right (always through an angle of 90 °C) with suction piping and delivery one right positioning or doing further measures (as installation of non-return organs) to prevent the pump spontaneous draining and to ensure its continuous flooding with a pumped liquid even in its stillstand.

Material options

Pump main parts are of following constructional materials:

Pump casing is of special cast iron or aluminium alloy.

Suction and discharge shields are of grey cast iron.

Screws are of heat-treated carbon steel.

Sense of rotation

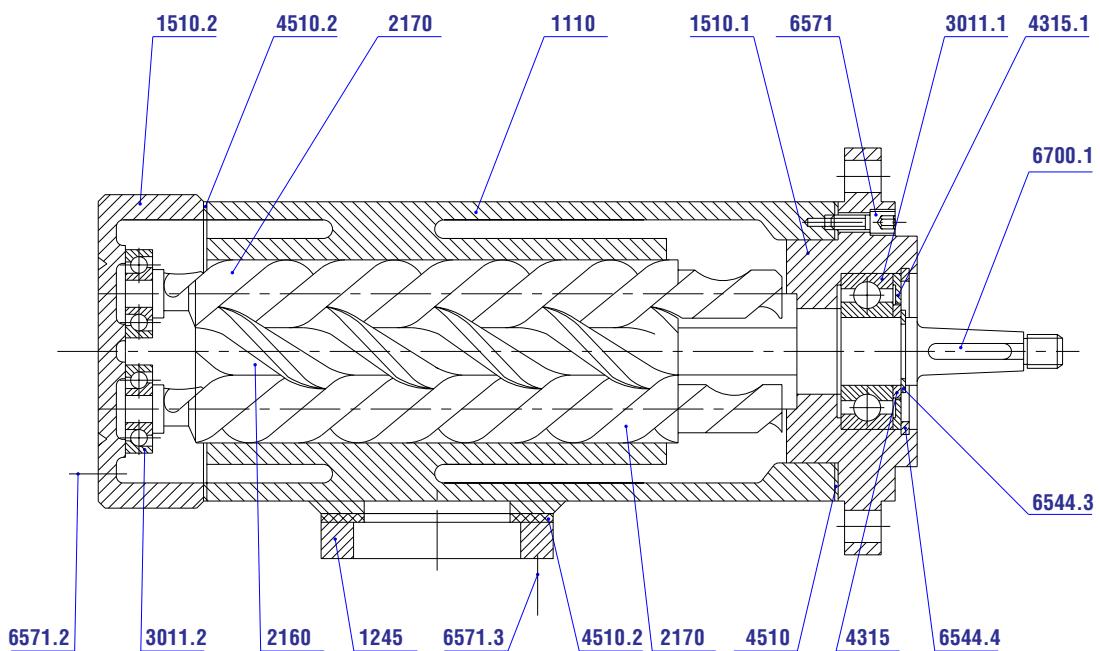

Pumps EAB and EAD may rotate both clockwise and counter-clockwise with unchanged arrangement of suction and discharge branches, considering direction of a pumped liquid flow. Sense of rotation shall be determined from the drive side. That pump may be used for the only one sense of rotation - for reverse sense of rotation it is necessary to use any other screws with reverse lead of an helix.

Locking organs

Those pump are not provided with their own locking organs. To prevent hazardous overloading due to pressure rise in an existing hydraulic system and its possible damage it is inevitable to protect the pump with the aid of a relief by-pass valve mounted into delivery piping close behind the pump but without any locking device being installed between a valve and the pump.

Performance data mentioned above are valid for $p_{s\ man} = 0$ bar

Q Pump capacity

P Pump power input

It is necessary to select a driving motor power output with corresponding capacity reserve according to the pump running-in conditions and its operating conditions, e.g. higher initial viscosity, long-run and/or continuous operations, and so on.

Permissible underpressure within speed range from 720 to 1,700 min⁻¹ and with kinematic viscosities from 21.5 to 380 mm².s⁻¹ shall be -0.5 bar with models from 32- to 50-EAB, EAD, or possibly -0.4 bar with models 65- and 100-EAB, EAD. With further speed ranges that value should be solved individually.

Max. inflow (positive suction head) for a pump in its standard model shall be 0.5 bar. With its special workmanship it may be $p_{s\ man} = 6$ bar.

Viscosity of a pumped liquid may range within values from 21.5 to 380 mm².s⁻¹. Within certain values of suction and discharge pressures and speed there viscosity values may range from 2.5 to 3,800 mm².s⁻¹.

Pump speed may be selected in accordance with viscosity and lubricating capacity of a pumped liquid working pressure and the pump size. It is possible to increase speed values mentioned in the Table - according to working conditions and by agreement with the manufacturer.
